Ballistic products represent a hazard for population due to the force of impact when falling and their high temperatures.

Area 1 HIGH HAZARD

Maximum radius of 5 km from the crater. Area most affected by the amount, frequency and power of falling ballistics.

Area 2 MODERATE HAZARD

Maximum radius of 8 km. Same affects than in Area 1, but less likely to occur.

Area 3 LOW HAZARD

Maximum radius of 14 km. Less likely to suffer damages by explosions accompanied by ballistics.

Ballistic products are fragments of volcanic material between 64 mm and a few meters in diameter. They are ejected from the crater into the atmosphere and fall down following a path similar to a parabolic curve. They can reach a top speed of 1,000 km/h, traveling several kilometers in under a minute.
